

# CS 465 Computer Security

---

RSA

# Recap

---

- Number theory
  - What is a prime number?
  - What is prime factorization?
  - What is a GCD?
  - What does relatively prime mean? What does co-prime mean?
  - What does congruence mean?
  - What is the additive inverse of  $13 \pmod{17}$  ?
  - What is the multiplicative inverse of  $7 \pmod{8}$  ?

# Recap: Diffie-Hellman

---

- You're trapped in your spaceship
- You have enough energy to send a single message to your HQ
- You have:
  - HQ's public DH values
    - $g=5$ ,  $p = 875498279345\dots$
    - $g^a = 32477230478\dots$
  - Your AES implementation from Labs #1 & 2
  - An arbitrary precision calculator
- How can you construct your message so that it will be safe from eavesdroppers?

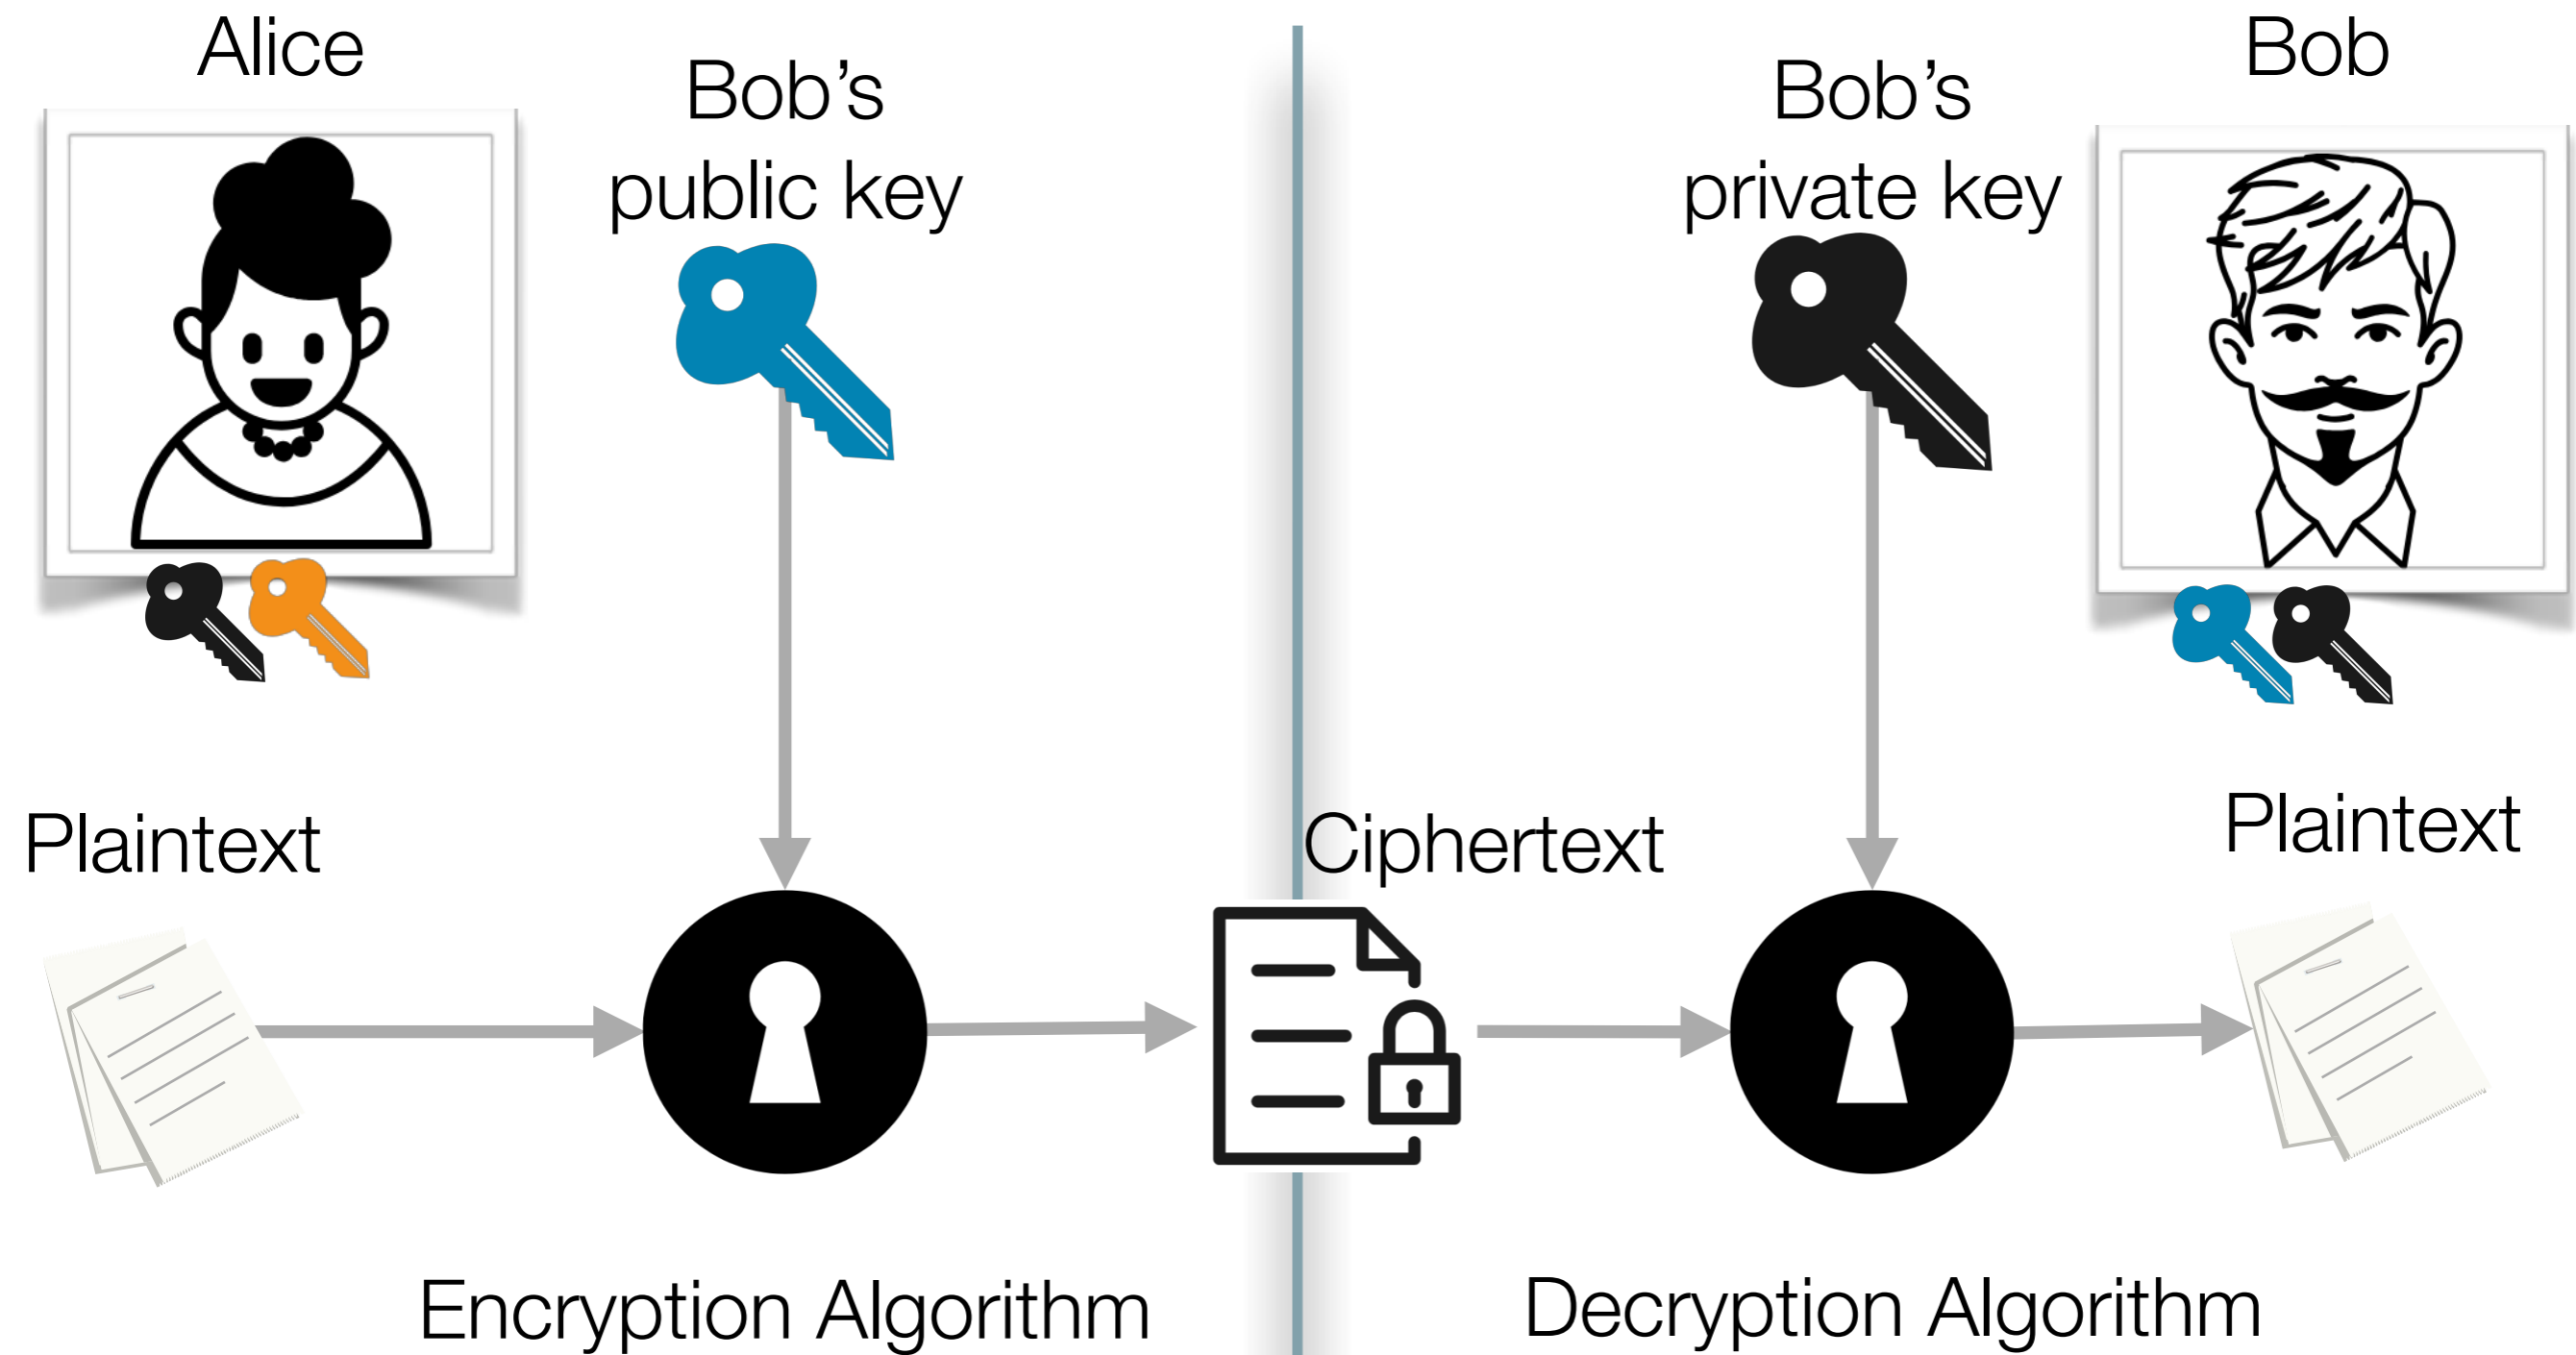

# Public Key Encryption

# Public Key Terminology

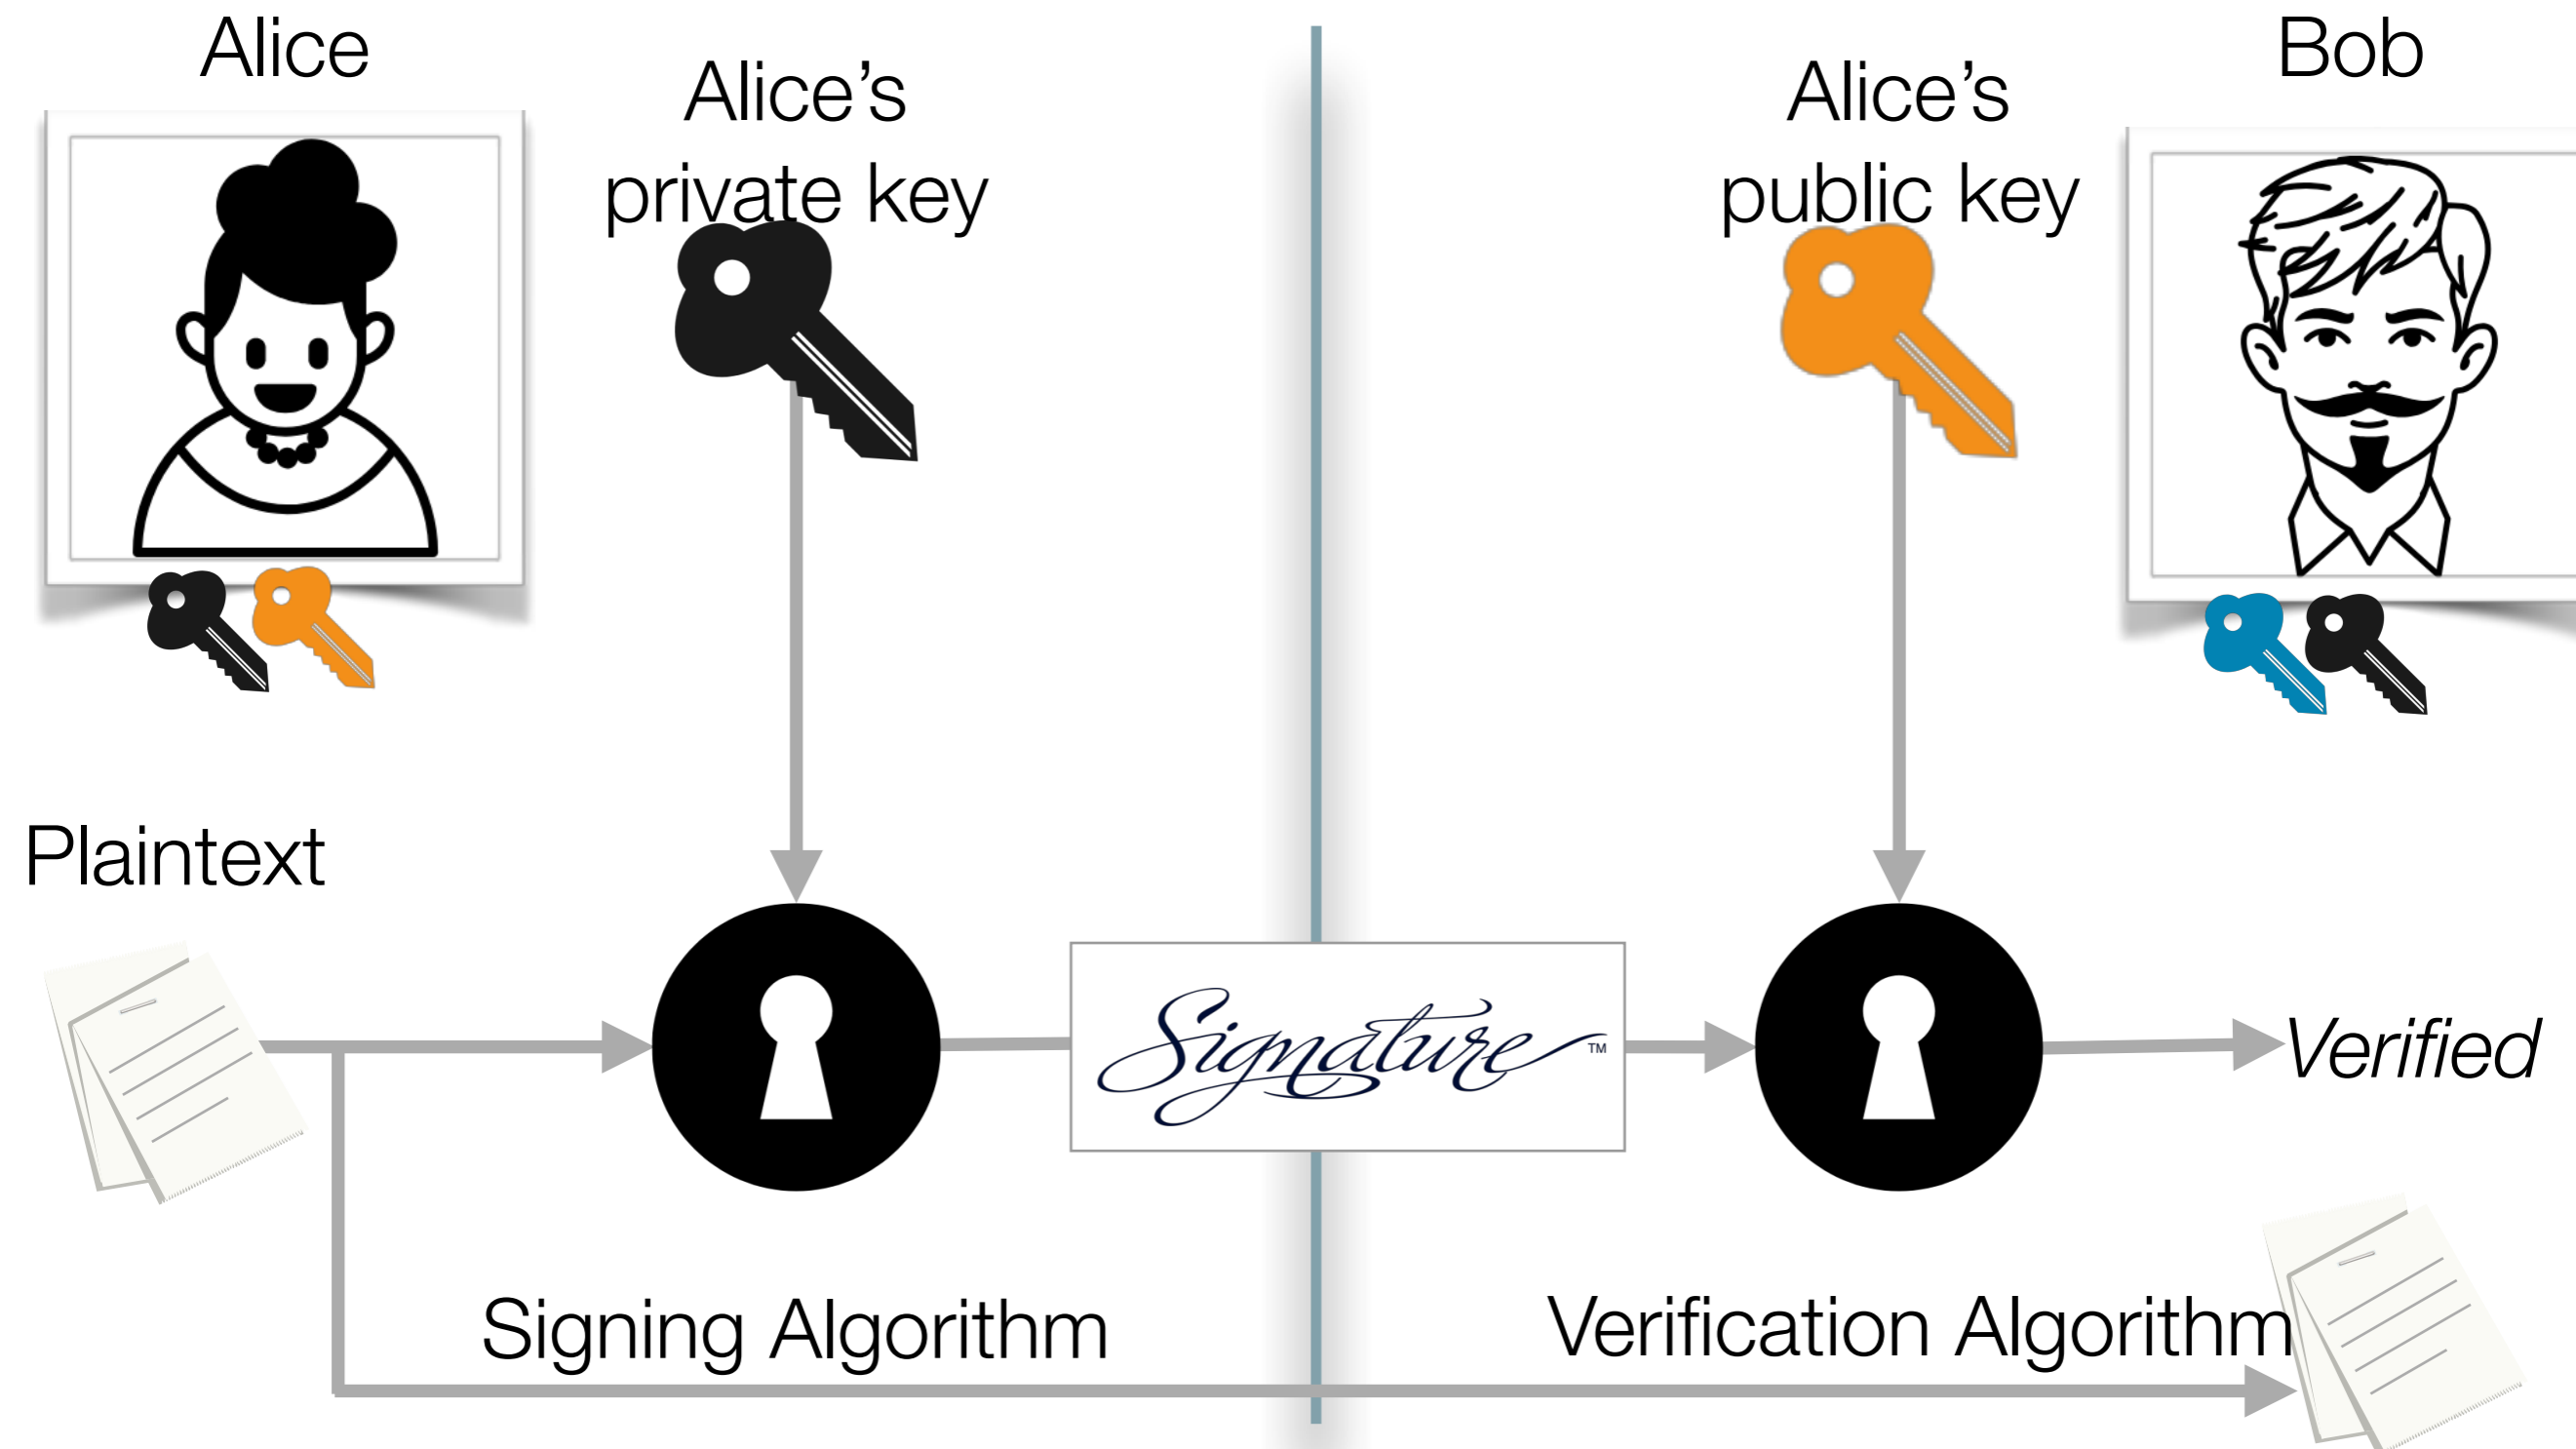

---

- Public Key
- Private Key
- Digital Signature
- You encrypt with a public key, and you decrypt with a private key
- You sign with a private key, and you verify with a public key

# Public Key Encryption Model

# Public Key Digital Signature Model

# History of RSA

---

- Invented in 1977 by Ron Rivest, Adi Shamir, Leonard Adleman
- Patented until 2000
- It's withstood years of extensive cryptanalysis
  - Suggests a level of confidence in the algorithm
  - Example of successful attacks against implementations
    - Side channel attacks
    - Poor random number generators

# Textbook RSA

---

- $m$  = message
- $c$  = ciphertext
- $e$  = public exponent
- $d$  = private exponent
- $n$  = modulus
  
- RSA Encryption:  $c = m^e \% n$
  
- RSA Decryption:  $m = c^d \% n$

# Why Public Key Encryption Works

# The Math Behind RSA

---

- RSA encrypt/decrypt operations are simple
- The math to get to the point where these operations work is not so simple (at first)
  - Fermat's little theorem
  - Euler's generalization of Fermat's little theorem

# Fermat's Little Theorem

---

- If
  - $p$  is prime
  - $a$  is not divisible by  $p$
- Then Fermat's theorem states
  - $a^{p-1} \equiv 1 \pmod{p}$  (Because  $a^p \equiv a \pmod{p}$ )
- This serves as the basis for
  - Fermat's primality test
  - Euler's generalization

Pierre de Fermat  
(1601-1655)

# Euler's Generalization of Fermat's Little Theorem

---

- Euler said

- $a^{\varphi(n)} \equiv 1 \pmod{n}$

n doesn't need to be prime  
a must still be co-prime to n

- $\varphi(n)$

- Euler's totient function
  - The number of values less than n which are relatively prime to n
  - Multiplicative group of integers ( $\mathbb{Z}_n^*$ )

- RSA is interested in values of n that are the product of two large prime numbers p and q

Leonhard Euler  
(1707-1783)

# Computing $\varphi(n)$ in RSA

---

- When  $p * q = n$ , and  $p$  and  $q$  are prime, what is  $\varphi(n)$ ?
- $\varphi(n)$  = the number of integers between 0 and  $n$  that are co-prime to  $n$
- Proof (When  $p * q = n$ )
  - Observations
    - 1) there are  $p-1$  multiples of  $q$  between 1 and  $n$
    - 2) there are  $q-1$  multiples of  $p$  between 1 and  $n$
    - These multiples are not co-prime to  $n$

$$(p-1)(q-1)$$

Why not?

Definition:

$$\varphi(n) = \# \text{ of values between } 0 \text{ and } n \text{ minus}$$
$$\# \text{ of values between } 0 \text{ and } n \text{ not relatively prime to } n$$

$$\begin{aligned}\varphi(n) &= [n - 1] - [(p-1) + (q-1)] \\ &= [pq - 1] - (p-1) - (q-1) \\ &= pq - p - q + 1 \\ &= (p-1)(q-1)\end{aligned}$$

# RSA

---

- Euler said:  $a^{\varphi(n)} \equiv 1 \pmod{n}$ 
  - $m^{(p-1)(q-1)} \equiv 1 \pmod{n}$
- Notice:  $m^{(p-1)(q-1)} * m \equiv m^{(p-1)(q-1)+1} \equiv m \pmod{n}$ 
  - $m^{\varphi(n)+1} \equiv m \pmod{n}$
- Let  $e*d = k*\varphi(n) + 1$ 
  - Then  $e*d \equiv 1 \pmod{\varphi(n)}$
  - Therefore  $m^{ed} \equiv m^{k*\varphi(n)+1} \equiv m^{\varphi(n)} * m^{\varphi(n)} * \dots * m \equiv m \pmod{n}$
- RSA encryption:  $m^e = c \pmod{n}$
- RSA decryption:  $c^d = m \pmod{n}$

## Why is RSA secure?

If you could factor  $n$  into  $p$  and  $q$ , then you know  $\varphi(n)=(p-1)(q-1)$ , and now you can easily calculate  $d$  ( $e$  is public).

This is called the “trap door” in RSA. Knowing the prime factors is what makes it easy to decrypt.

It’s hard to factor large primes and hard to find  $d$  without knowing the factorization.

# How To Use Public Key Encryption

# Steps for RSA Encryption

---

- Select  $p$ ,  $q$  (large prime numbers)
- $n = p * q$
- $\varphi(n) = (p-1)(q-1)$
- Select integer  $e$  where  $e$  is [relatively prime](#) to  $\varphi(n)$ 
  - Common values for  $e$  are 3 and 65537. Why?
- Calculate  $d$ , where  $d * e = 1 \pmod{\varphi(n)}$
- Public key is  $KU = \{e, n\}$
- Private key is  $KR = \{d, n\}$

# RSA Usage

---

- Given  $m^e = c \pmod{n}$  and  $c^d = m \pmod{n}$ 
  - What restrictions should be placed on  $m$ ?
- For bulk encryption (files, emails, web pages, etc)
  - Never, never, never encrypt data directly using RSA — inefficient and insecure
  - Always use symmetric encryption for data, and use RSA to encrypt the symmetric key, using a secure padding scheme
- Digital signatures
  - Do not sign the entire document — too slow
  - Sign (encrypt) a hash of the document using the private key

# How To Calculate RSA Values

# How do we get $p$ , $q$ , $e$ , and $d$ ?

---

- What is  $p$ ?
  - How do we get it?
- What is  $q$ ?
  - How do we get it?
- What is  $e$ ?
  - How do we get it?
  - What is the relationship of  $e$  and  $(p-1)(q-1)$ ?
- What is  $d$ ?
  - How do we get it?

# Recap

---

- $n=p^*q \rightarrow \varphi(n) = (p-1)(q-1)$
- Choose  $e*d = K \varphi(n)+1 \rightarrow e \mathbf{e*d} \equiv \mathbf{1 (mod \varphi(n))}$
- $m^{ed} \equiv m^{k*\varphi(n)+1} \equiv m^{\varphi(n)} * m^{\varphi(n)} * \dots * m \equiv m \pmod{n}$
- Select integer e where e is relatively prime to  $\varphi(n)$
- Calculate d, where  $\mathbf{d*e = 1 (mod \varphi(n))}$

# Calculating d

---

- Goal: find  $d$  such that  $ed = 1 \pmod{\varphi(n)}$  – Use the extended Euclidean algorithm
- Based on the fact that GCD can be defined recursively
  - If  $x > y$ , then  **$\text{GCD}(x,y) = (\text{recursively}) \text{GCD}(y, x-y)$**
  - Also if  $x > y$ , then  **$\text{GCD}(x,y) = (\text{recursively}) \text{GCD}(y, x\%y)$**
- GCD can also be used as follows:
  - Suppose  **$ax + by = \text{gcd}(x,y)$**
  - If  $x$  is the modulus, and  $\text{gcd}(x,y) = 1$ 
    - Then  $ax + by = 1$  and  $b$  is  $y^{-1}$

# Calculating d

---

- Goal: find  $d$  such that  $ed = 1 \pmod{\varphi(n)}$
- Use the extended Euclidean algorithm
  - Calculates  $x$  and  $y$  such that  $ax+by=\text{gcd}(a,b)$
  - Let  $a=e$ ,  $b=\varphi(n)$ .  $\text{gcd}(e,\varphi(n))=1$  because they are co-prime
  - Then you have:  $ex+\varphi(n)y=1$
  - Take this modulo  $\varphi(n)$  and you get:  $ex \equiv 1 \pmod{\varphi(n)}$
  - $x=d$  (if  $x$  is negative, simply add  $\varphi(n)$ )

# Extended Euclidean Algorithm

---

- Let  $p = 5$ ,  $q = 11$ ,  $n = 55$ ,  $e = 17$ , and  $\varphi(n) = 40$

- $17d + 40k = 1$

- $40 = 2 \times 17 + 6$       GCD with remainder

- $17 = 2 \times 6 + 5$       GCD with remainder

- $6 = 1 \times 5 + 1$       (stop at remainder 1)

- Rewrite

- $6 - 1 \times 5 = 1$

- Substitute

- $6 - 1 \times 5 = 1$

- $6 - 1 \times (17 - 2 \times 6) = 1$

- $(40 - 2 \times 17) - 1 \times (17 - 2 \times (40 - 2 \times 17)) = 1$

- Simplify

- $(-7) \times 17 + 3 \times 40 = 1$

- $d = -7 \rightarrow$  add 40 (the modulus) and get  $d = 33$

- Public key =  $\{17, 55\}$

- Private key =  $\{33, 55\}$

# Practice

---

$p=5, q=11, e=3$

# Practice

---

$$p=5, q=11, e=3$$

$$n = p \cdot q = 55$$

$$\varphi(n) = (p-1)(q-1) = 4 \cdot 10 = 40$$

Calculate d

$$3 \cdot d + 40 \cdot k = 1$$

$$40 = 13 \cdot 3 + 1$$

(no substitution steps needed)

$$(-13) \cdot 3 + 40 = 1$$

$$d = -13 + 40 = 27$$

Public Key = {3, 55}

Private Key = {27, 55}

An Exception!

# GCD(e, $\varphi(n)$ ) must be 1

---

- Be sure to check, otherwise you need a new e
- Easy algorithm:
  - $\text{GCD}(x, y) = \text{GCD}(y, x \% y)$  if  $x > y$  (recursive computation)
- Example
  - $\text{GCD}(40, 3) = \text{GCD}(3, 1) = 1$
  - $\text{GCD}(120, 3) = 3!$

# Practice

---

$p=11, q=13, 2 < e \leq 8$

# Practice

---

$$p=11, q=13, 2 < e \leq 8$$

$$n = p \cdot q = 143$$

$$\varphi(n) = (p-1)(q-1) = 10 \cdot 12 = 120$$

Calculate d

$$\text{GCD}(\varphi(n), e) = \text{GCD}(120, 3) = 3, \text{GCD}(120, 5) = 5, \text{GCD}(120, 7) = \text{GCD}(17, 1) = 1$$

$$7 \cdot d + 120 \cdot k = 1$$

$$120 = 17 \cdot 7 + 1$$

(no substitution steps needed)

$$(-17) \cdot 7 + 120 \cdot 1 = 1$$

$$d = -17 + 120 = 103$$

$$\text{Public Key} = \{7, 143\}$$

$$\text{Private Key} = \{103, 143\}$$

More Practice

# Practice

---

$p=5, q=13, e=5$

# Practice

---

$$p=5, q=13, e=5$$

$$n = p*q = 65$$

$$\varphi(n) = (p-1)(q-1) = 4*12 = 48$$

Calculate d

$$\text{GCD}(\varphi(n), e) = \text{GCD}(48, 5) = \text{GCD}(5, 3) = \text{GCD}(3, 2) = 1$$

$$5*d + 48*k = 1 \quad (\text{notice how these match the substitution steps})$$

$$48 = 9*5 + 3$$

$$5 = 1*3 + 2$$

$$3 = 1*2 + 1$$

(substitute)

$$3 - 1*2 = 1$$

$$3 - 1*(5 - 1*3) = 1$$

$$48 - 9*5 - 1*(5 - 1*(48 - 9*5)) = 1$$

$$48 - 9*5 - 1*5 + 1*48 - 9*5 = 1$$

$$2*48 - 19*5 = 1$$

$$d = -19 + 48 = 29$$

Public Key = {5, 65}

Private Key = {29, 65}

# Practice

---

$p=17, q=11, e=7$

# Practice

---

$$p=17, q=11, e=7$$

$$n = p \cdot q = 187$$

$$\varphi(n) = (p-1)(q-1) = 16 \cdot 10 = 160$$

Calculate d

$$\text{GCD}(\varphi(n), e) = \text{GCD}(160, 7) = \text{GCD}(7, 6) = 1$$

$$7 \cdot d + 160 \cdot k = 1$$

$$160 = 22 \cdot 7 + 6$$

$$7 = 1 \cdot 6 + 1$$

(substitute)

$$7 - 1 \cdot 6 = 1$$

$$7 - 1 \cdot (160 - 22 \cdot 7) = 1$$

$$7 - 160 + 22 \cdot 7 = 1$$

$$23 \cdot 7 - 1 \cdot 160 = 1$$

$$d = 23$$

Public Key = {7, 187}

Private Key = {23, 187}
